Design for accessibility

We design products that work for everyone — regardless of how they see, hear, or navigate — built to WCAG standards from the start, not patched in after launch.

Usable by everyone, by design

DEFINITION

“Built in, not bolted on.”

Accessibility design ensures a digital product can be used by everyone, including people with disabilities — through clear structure, sufficient contrast, keyboard navigation, and support for assistive technology like screen readers.

THE FOUR WCAG PILLARS

— **Perceivable**
Content works regardless of how it’s presented.

— **Operable**
Every interaction works by keyboard, not just a mouse.

— **Understandable**
Clear language and predictable navigation.

— **Robust**
Reliable across browsers and assistive tech.

Contrast isn't a matter of taste

WCAG puts real thresholds on legibility. Step through the samples to see where text stops being readable — and which conformance level it clears.

Low contrast · Large only · **Passes AA** · Passes AAA

Everyone should read this.

Body copy at this contrast is what a real user has to work through, line after line.

CONTRAST RATIO
6.1:1

AA — normal text · 4.5:1	PASS
AA — large text · 3:1	PASS
AAA — normal text · 7:1	FAIL

— **Perceivable**
Enough contrast, resizable text, and structure that survives however it’s presented.

— **Operable**
Every control reachable and usable by keyboard, with visible focus states.

— **Understandable**
Plain language and navigation that behaves the way people expect.

— **Robust**
Marked up so browsers and assistive tech read it reliably.

Cheaper, safer, and better for every user

Most issues start at design
The majority of accessibility problems can be prevented before a single line of code is written.

Often a legal requirement
Many countries now mandate digital accessibility, with WCAG as the referenced technical standard.

Better for everyone
Clear contrast, simple navigation, and legible text improve usability across the board, not only for users with disabilities.

Avoids costly rework
Fixing accessibility after launch is far more expensive than designing for it from the start.

Six principles behind the work

01 **Perceivable**
Content works regardless of how it’s presented to the user.

02 **Operable**
Every interaction works via keyboard, not just a mouse.

03 **Understandable**
Clear language and predictable, consistent navigation.

04 **Robust**
Works reliably across browsers and assistive technology.

05 **Sufficient contrast**
Text and interface elements meet real WCAG thresholds.

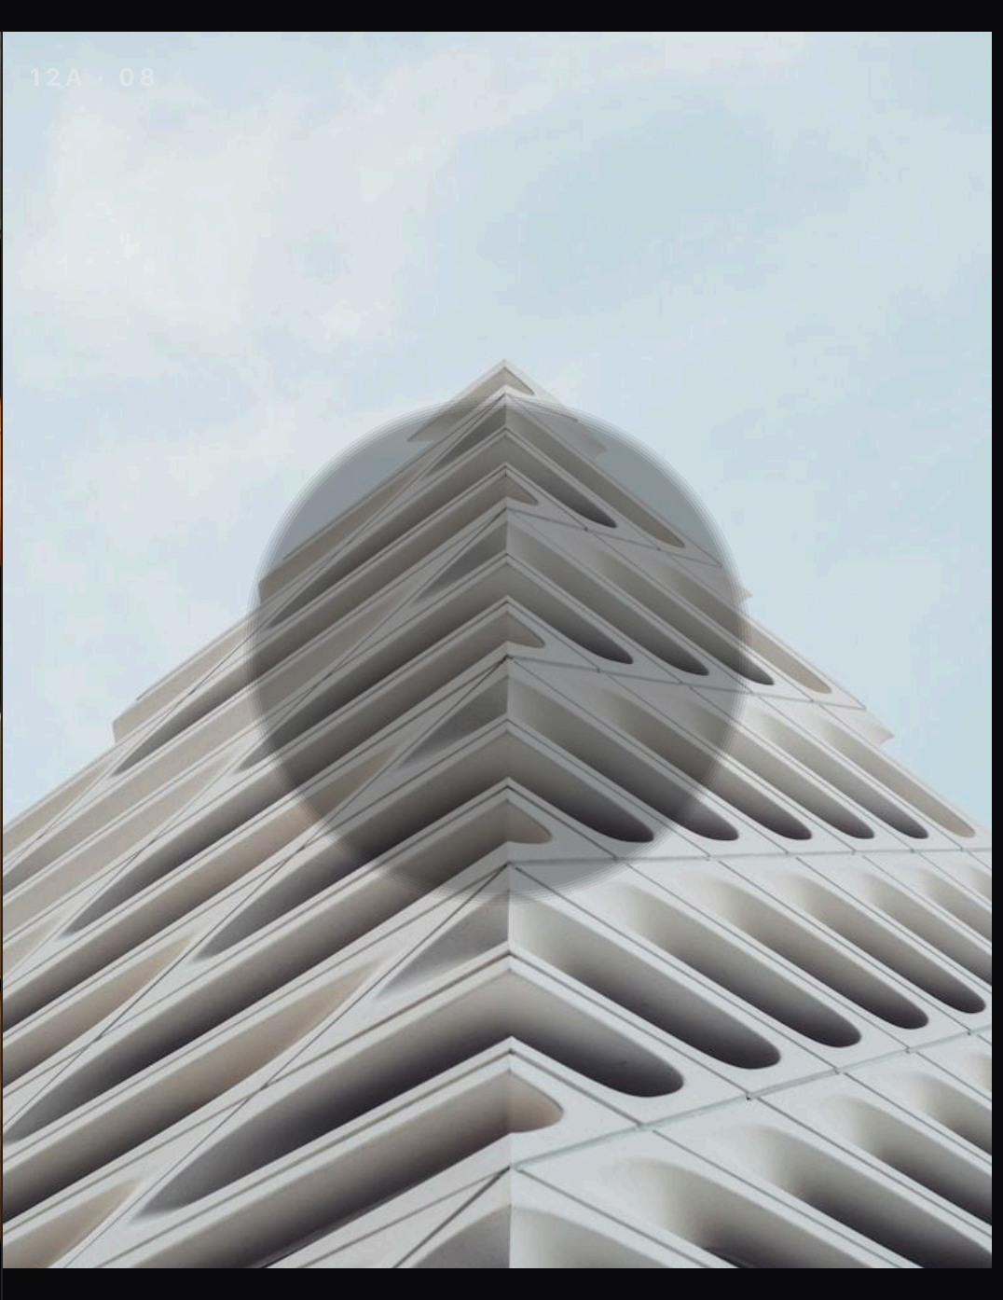
06 **Tested with real users**
Validated with people, not just automated tools.

Designed for everyone, in the wild

A few frames off the sheet — products built to WCAG from the first wireframe.

SOLID
Building modern banking-as-a-service experiences
View case →

UPGRAD
Powering informed course decisions on the study-abroad platform
View case →



EMAAR
Digitizing property worth $1Bn+

COMMON QUESTIONS

Frequently asked questions

01 What is WCAG, and which level do we need? ×

WCAG is the international standard for digital accessibility, with three conformance levels — A, AA, and AAA. Most organizations target AA, which covers things like a 4.5:1 contrast ratio and full keyboard navigation. We’ll help you decide what’s right based on your industry and region.

02 Is accessibility just about screen readers? +

03 Can we fix accessibility after the product is already built? +

04 What do I get at the end? +

Not sure if your product *actually works for everyone?*

Point us at your product and the standard you need to meet. We'll audit it against WCAG, prioritise the fixes, and give your team guidance to build on.
