UX for AI products

AI behaves differently from traditional software — probabilistic, sometimes wrong, hard to predict. We design for that: control, transparency, and trust built into every interaction.

Designing for systems that guess

AI products predict, recommend, or generate rather than follow fixed rules. The interface has to do more than traditional software — because the output can be wrong.

Traditional software

“Same input, same output.”

Deterministic and predictable. The interface can assume the system did exactly what it was told, so it mostly needs to stay out of the way.

AI product

“Probably right — here's why.”

Probabilistic and uncertain. The interface has to show what the system is doing, let users correct it, and set the right expectations before something goes wrong.

Anatomy of an interaction users trust

The same AI output, designed to be legible: a confidence signal, the reasoning behind it, and a way out. Hit Regenerate to see how the interface holds up as certainty drops.

AI suggestion 88% · High confidence

Route this ticket to Billing — most likely a double charge.

WHY THE MODEL THINKS SO

Mentions “charged twice”	74%
Recent payment error on account	61%
Similar tickets resolved by Billing	52%

Edit Override Regenerate

High confidence — but the user can still override before it routes.

Confidence, shown
A number and a colour, not a flat answer dressed up as fact.

Reasoning, exposed
The factors that drove the call — so a person can sanity-check it.

Control, always
Edit, override, or regenerate — the user is never stuck with the guess.

Graceful low confidence
When the model is unsure, the interface says so and defers to a human.

A wrong answer users can catch beats a confident black box

Trust has to be designed in
Users won’t rely on an AI feature they don’t understand or can’t predict.

Errors work differently
AI fails unpredictably, not like a traditional bug — the interface needs fallback paths and clear recovery, not just error messages.

Control keeps users confident
Letting people edit, override, or regenerate output matters more than getting it right every time.

Explainability builds adoption
Showing why a recommendation or score appeared turns a black box into something users will actually act on.

Six principles behind the work

01
Design for uncertainty

We design for the range of outputs a model can produce, not just the correct one.

02
Explain the reasoning

03
Give users control

Designed in the wild

A few frames off the sheet — AI features built to be understood, corrected, and trusted.

Frequently asked questions

- How is designing for AI different from designing regular software? +
- How do you handle it when the AI gets something wrong? +
- What does “explainability” actually mean in an interface? +
- What do I get at the end? +

Building an AI feature *users will actually trust?*

Tell us what your AI does and where it's uncertain. We'll design the interaction patterns confidence, control, and recovery — around how it actually behaves.
